# Chapter 1. Introduction

This guide describes how to download, install and run the Technology Compatibility Kit (TCK) for the Jakarta MVC Specification 3.0.

## 1.1. TCK Primer

A TCK, or Technology Compatibility Kit, is one of the three required pieces for any JSR (the other two being the specification document and the reference implementation). The TCK is a set of tools and tests to verify that an implementation of the technology conforms to the specification. The tests are the primary component, but the tools serve an equally critical role of providing a framework and/or set of SPIs for executing the tests.

The tests in the TCK are derived from assertions in the written specification document. The assertions are itemized in an XML document, where they each get assigned a unique identifier, and materialize as a suite of automated tests that collectively validate whether an implementation complies with the aforementioned assertions, and in turn the specification. For a particular implementation to be certified, all the required tests must pass (meaning the provided test suite must be run unmodified).

A TCK is entirely implementation agnostic. It should validate assertions by consulting the specification's public API.

## 1.2. Compatibility Testing

The goal of any specification is to eliminate portability problems so long as the program which uses the implementation also conforms to the rules laid out in the specification.

Executing the TCK is a form of compatibility testing. It's important to understand that compatibility testing is distinctly different from product testing. The TCK is not concerned with robustness, performance or ease of use, and therefore cannot vouch for how well an implementation meets these criteria. What a TCK can do is to ensure the exactness of an implementation as it relates to the specification.

Compatibility testing of any feature relies on both a complete specification and a complete reference implementation. The reference implementation demonstrates how each test can be passed and provides additional context to the implementor during development for the corresponding assertion.

## 1.3. About the MVC TCK

The Jakarta MVC 3.0 TCK is designed as a portable, configurable and automated test suite for verifying the compatibility of an implementation of the Model-View-Controller Specification. The test suite is built atop JUnit and provides a series of extensions that allow runtime packaging and deployment of Java EE artifacts for in-container testing (Arquillian).

Each test class in the suite acts as a deployable unit. The deployable units, or artifacts, are defined

in a declarative way using annotations.

## 1.4. TCK Components

The Jakarta MVC 3.0 TCK includes the following components:

- **The test suite**, which is a collection of JUnit tests and supplemental resources that configure the runtime and other software components.
- **The TCK audit** (`tck-audit.xml`) used to list out the assertions identified in the Jakarta MVC 3.0 specification. It matches the assertions to test cases in the test suite by unique identifier and produces a coverage report. The audit document is provided along with the TCK. Each assertion is defined with a reference to a chapter, section and paragraph from the specification document, making it easy for the implementor to locate the language in the specification document that supports the feature being tested.
- A **setup example** demonstrating Maven and Ant setups to run the TCK test suite.

## 1.5. Passing the Jakarta MVC 3.0 TCK

In order to pass the Jakarta MVC 3.0 TCK, you need to:

- Pass the Jakarta MVC 3.0 signature tests (see [Running the signature tests](#)) asserting the correctness of the Jakarta MVC 3.0 API used.
- Run and pass the test suite (see [Running the TCK tests](#)).

## Chapter 2. TCK Challenge and resolution process for Jakarta MVC

This specification allows for lazy consensus as a resolution path for TCK test challenges as described in the Jakarta EE TCK Process Guide. For this specification, test challenges will be deemed accepted, 14 days from the date the test challenge issue is filed. Please file your challenge in conformance with "Filing a Challenge" requirements in the TCK Process Guide. If any specification team member determines that the challenge requires review it should be marked with the tag **challenge-review** and it will be resolved under the *Active Resolution* process as described in the Jakarta EE TCK Process guide. Generally, once a conversation occurs with a member of the committer team, the filer should consider that the challenge will follow the Active Resolution process.

In the event a challenge is approved under lazy consensus, any vendor implementation Compatibility Certification Request (CCR) that uses this challenge must include the issue ID along with the TCK details and test reporting statistics for this specification, regardless if the CCR is filed to this specification project issue tracker, or it is filed for any other specification project issue tracker. Failure to include this issue reference could result in CCR approval delay.

Once a TCK revision, that includes the resolution of this challenge is released, it is no longer necessary to include any additional reference in your CCR.

This specification team tries to track issues as they are filed but feel free to reach out to us via [mvc-dev@eclipse.org](mailto:mvc-dev@eclipse.org). If that fails, you may escalate your issue to the Jakarta EE Platform Committer list [jakartaee-platform-dev@eclipse.org](mailto:jakartaee-platform-dev@eclipse.org). If it is necessary to escalate further, you may request action following the Grievance process as described in the Eclipse Development Process, Handbook under Grievance Handling.

# Chapter 3. Coverage report

A specification can be distilled into a collection of assertions that define the behavior of the software. This section introduces the Jakarta MVC 3.0 TCK coverage report, which documents the relationship between the assertions that have been identified in the Jakarta MVC 3.0 specification document and the tests in the TCK test suite.

The structure of this report is controlled by the assertion document, so we'll start there.

## 3.1. Jakarta MVC 3.0 TCK Assertions

The Jakarta MVC 3.0 TCK developers have analyzed the Jakarta MVC 3.0 specification document and identified the assertions that are present in each chapter.

The assertions are listed in an XML file which is generated from the specification document. Each assertion is identified by the section of the specification document in which it resides and a unique paragraph identifier to narrow down the location of the assertion further.

See the following example of an example:

```
<section id="controllers" title="Controllers" level="2">
  <!-- ... -->
  <assertion id="ctrl-method">
    <text>An MVC controller is a JAX-RS resource method decorated by @Controller</text>
  </assertion>
  <!-- ... -->
</section>
```

The strategy of the Jakarta MVC 3.0 TCK is to write a test which validates this assertion when run against an implementation. A test case (a method annotated with `@Test`) is correlated with an assertion using the `@org.jboss.test.audit.annotations.SpecAssertion` annotation as follows:

```
@RunWith(Arquillian.class)
@SpecVersion(spec = "mvc", version = "1.0")
public class ControllerAnnotationTest {

    /* more tests */

    @Test
    @SpecAssertion(section = Sections.MVC_CONTROLLERS, id = "ctrl-method")
    public void controllerMethod() throws IOException {
        // test implementation
    }

    /* more tests */

}
```

To help evaluate the distribution of coverage for these assertions, the TCK provides a detailed coverage report. This report is also useful to help implementors match tests with the language in the specification that supports the behavior being tested.

## 3.2. The Coverage Report

The coverage report is an HTML report generated as part of the TCK project build. Specifically, it is generated by an annotation processor that attaches to the compilation of the classes in the TCK test suite. The report is written to the directory `tests/target/coverage-report/`.

The report itself has three main sections:

### Chapter Summary

List the chapters in the specification document along with total assertions, tests and coverage percentage.

### Section Summary

Lists the sections in the specification document along with total assertions, tests and coverage percentage.

### Coverage Detail

Each assertion and the test that covers it, if any.

The coverage report is color coded to indicate the status of an assertion, or group of assertions. The status codes are as follows:

#### Covered

Test exists for this assertion

#### Not covered

No test exists for this assertion

#### Unimplemented

A test exists, but is unimplemented

#### Untestable

the assertion has been deemed untestable, a note, explaining why, is normally provided

For reasons provided in the `tck-audit.xml` document and presented in the coverage report, some assertions are not testable.

# Chapter 4. Running the TCK tests

This chapter describes how to run and configure the TCK test suite against a given Jakarta MVC 3.0 implementation in a given Java EE container. The testsuite uses [Arquillian](#) to execute tests against real Java EE containers. It is strongly recommended making yourself familiar with the Arquillian documentation. It will give you a deeper understanding of the different parts described in the following sections.

## 4.1. The TCK runner template

The TCK contains a directory `sample` which contains an example project for running the TCK and which should be used as a template for creating new projects. This sample project is using the reference implementation Eclipse Krazo and runs the TCK against Eclipse Glassfish 8.x.

The project is using Apache Maven and contains just three files:

### `pom.xml`

The Maven POM file imports the TCK BOM, declares all required dependencies and configures the Maven Surefire Plugin to run the tests defined by the Jakarta MVC 3.0 TCK.

### `arquillian.xml`

This file configures Arquillian to deploy the web applications which are used by the TCK tests to Eclipse Glassfish.

### `KrazoGlassfishProvider.java`

This Java class is an implementation of the `ee.jakarta.tck.mvc.api.BaseArchiveProvider` interface which is part of the TCK. The responsibility of the archive provider is to create a base Shrinkwrap archive which is used by all TCK tests. The archive produced by the provider depends on the specific environment you are running the tests against. As Jakarta MVC 3.0 API and implementation is not provided by Eclipse Glassfish, the `KrazoGlassfishProvider` builds an archive which adds the API JAR and Eclipse Krazo to the `/WEB-INF/lib` directory of the archive so that both are deployed as part of the web application.

Running the TCK is simple. First you have to download, unpack and start Eclipse GlassFish 8.x. Then just execute the following command in the sample project folder to run the TCK against this Eclipse GlassFish 8.x instance:

```
mvn verify
```

After a few minutes you should get an output like this:

```
[...]
Running org.mvc.spec.tck.tests.mvc.controller.mediatype.MediaTypeTest
Tests run: 2, Failures: 0, Errors: 0, Skipped: 0, Time elapsed: 1.109 sec - in
org.mvc.spec.tck.tests.mvc.controller.mediatype.MediaTypeTest
Running org.mvc.spec.tck.tests.mvc.controller.inject.InjectParamsTest
Tests run: 5, Failures: 0, Errors: 0, Skipped: 0, Time elapsed: 1.047 sec - in
org.mvc.spec.tck.tests.mvc.controller.inject.InjectParamsTest
```

Results :

Tests run: 132, Failures: 0, Errors: 0, Skipped: 0

[...]

[INFO] -----

Congratulations! You just ran the Jakarta MVC 3.0 TCK!

## 4.2. Adjusting the template project

If you want to run the Jakarta MVC 3.0 TCK against a different environment, you should start from the template project and adjust it like described in the following sections.

## 4.3. Update Arquillian configuration

If you want to run the TCK against a different container, you will typically have to adjust the Arquillian configuration. In most cases this is really easy, because Arquillian already supports a wide range of containers. However, it is strongly recommended having a deeper look at the [Arquillian documentation](#) to learn more.

Generally, you will have to follow these steps:

- Replace the `arquillian-glassfish-remote-3.1` Arquillian adapter with the adapter for your environment in the `pom.xml` file.
- Then adjust the `arquillian.xml` file as described in the Arquillian adapter documentation. This typically includes adjusting port numbers and providing credentials for performing remote deployments.

As mentioned above, the details depend on the specific environment.

## 4.4. Provide a custom BaseArchiveProvider

The `BaseArchiveProvider` is used by the TCK to create a base web application archive capable of running Jakarta MVC 3.0 application in the specific target environment. The TCK then just adds controllers, views and other artifacts to that base archive and deploys it to the target container.

As the template project runs the TCK against Eclipse Glassfish 6.0.0 which doesn't provide support for Jakarta MVC 3.0 out of the box, the corresponding archive provider creates a web application archive which includes both the Jakarta MVC 3.0 API JAR and the reference implementation Eclipse Krazo in `/WEB-INF/lib`.

The default implementation provided with the template project looks like this:

```

public class KrazoGlassfishProvider implements BaseArchiveProvider {

    @Override
    public WebArchive getBaseArchive() {

        File[] dependencies = Maven.resolver()
            .resolve(
                "jakarta.mvc:jakarta.mvc-api:3.0.1",
                "org.eclipse.krazo:krazo-core:3.0.0",
                "org.eclipse.krazo:krazo-jersey:3.0.0"
            )
            .withoutTransitivity()
            .asFile();

        return ShrinkWrap.create(WebArchive.class)
            .addAsLibraries(dependencies);

    }

}

```

You will have to create a similar class which does the same for the environment you want to run the test against.

If your container provides Jakarta MVC 3.0 support out of the box, you would have to create an implementation which returns an empty archive like this:

```

public class EmptyArchiveProvider implements BaseArchiveProvider {

    @Override
    public WebArchive getBaseArchive() {
        return ShrinkWrap.create(WebArchive.class);
    }

}

```

The TCK uses a Java system property to learn about the implementation that should be used for building archives. This system property is configured using the Maven Surefire Plugin configuration in your `pom.xml`. The relevant section in the template project looks like this:

```

<plugin>
  <artifactId>maven-surefire-plugin</artifactId>
  <version>2.19.1</version>
  <configuration>
    <dependenciesToScan>jakarta.mvc.tck:mvc-tck-tests</dependenciesToScan>
    <systemProperties>
      <BaseArchiveProvider>
        jakarta.mvc.tck.runner.KrazoGlassfishProvider
      </BaseArchiveProvider>
    </systemProperties>
  </configuration>
</plugin>

```

```
        </BaseArchiveProvider>
    </systemProperties>
</configuration>
</plugin>
```

If you provide a custom implementation of `ArchiveBaseProvider`, you will have to adjust the configuration and change the FQCN if the implementation class.

# Chapter 5. Running the signature tests

The signature file bundled inside this TCK is created using the <https://github.com/eclipse-ee4j/jakartaee-tck-tools/tree/master/tools/sigtest> [SigTest Maven plugin]. The same plugin can be used to run a signature test to check for any incompatibilities. Let's take a look how it can be done as a part of a Maven build. Note that there must be no dependency declared for this project besides the API artifact you wish to test.

Before running an actual test you need to obtain the signature file first. It is included inside the validation tck distribution artifacts subdirectory as vmvc-tck-sigtest-3.0.0.sigfile.

To actually run a signature test, the check goal of the sigtest-maven-plugin can be used. The TCK distribution sample/sigtest-pom.xml includes a sigtest profile that can be used to run the signature test.

Running it should produce the following output:

```
[INFO] SignatureTest report
Base version: 3.0.0
Tested version: 3.0.0
Check mode: bin [throws removed]
Constant checking: on
```
