call-back mini HOWTO

by Pawel Skonecki, stona@fizyka.umcs.lublin.pl

v1.1a, June 2000

This document describes how to set up call-back by using the Linux system and modem. I would like to thank Anna for her patience.

1. [Introduction](#)

1.1 OPINION

I'll be waiting for all opinions about this document. I have tried to gather information as complete as possible. Tell me when you find any mistakes. I'll be grateful to people who will send me any suggestions or corrections. Their contributions will make this document better. I don't mind answering your questions but I'd rather you read the whole article first.

1.2 PUBLISHING

This document can be published under the conditions of Linux Documentation Project. Get in touch with the author if you can't get this license. This document is free.

2. [Procedure](#)

2.1 PART I: Net at home ?

Most of us use the Internet in a place of work. However we often need the net at home or outside the place of work. It may be possible that the work from home is cheaper than from a company building. I think that the best solution is to install call-back software on the Linux server. Call-back makes it possible to re-call index number at the cost of the company. I'll try to present how it works. An entitled person calls modem is varied for the first time in Linux server. Then on the user's side the "hang up modem" is switched on. At the same time Linux calls the user. User is verified again. We have connection and the server is charged. The user pays only for the initiation of connection. The double verification and extra options in the call-back program enable the unsuitable persons to charge our bill. We can restrict the access to the connection only to corporation network or Internet. Call-back is very flexible. Below, I'll try to present the configuration of a call-back server on Linux system and I'll show you how to set up your computer for re-calling the connection.

2.2 PART II: The first steps with modem.

The administrators prefer different modem but while buying a modem we should remember about certain rules:

- Don't buy the Win-Modem because it doesn't work with Linux
- The external modem works faster than the modem which is inside your computer
- The internal modem with ISA slot is better than the one with PCI slot (you can use your PCI slot for something different)
- Don't use Plug&Play modem. If you have it set off, Plug&Play options and set up modem on free com (read Plug&Play-HOWTO).

When we have the suitable modem we have to set it up in our system. We have to check on which com our modem is. Then we have to make a symbolic link to this hardware and /dev/modem. For example, if we have the modem for the 2nd com we write:

```
ln -s /dev/cua1 /dev/modem
```

We check it

call-back mini HOWTO

```
lrwxrwxrwx 1 root uucp 9 Sep 19 19:10 /dev/modem -> /dev/cua1
```

If we have the modem on different com we have to remember that

```
/dev/cua0 is com1
```

```
/dev/cua1 is com2
```

```
/dev/cua2 is com3
```

```
/dev/cua3 is com4
```

For new kernels:

```
/dev/ttyS0 is com1
```

```
/dev/ttyS1 is com2
```

```
/dev/ttyS2 is com3
```

```
/dev/ttyS3 is com4
```

Now, we check our configuration using the program minicom.

2.3 PART III Call Linux

The first step to make the call-back on Linux accessible is to set up a suitable parameter in kernel. Then we check whether our kernel serves the protocol ppp. If you don't have ppp in your kernel or in module you will have to compile your kernel and add ppp. You will find more information in Kernel-HOWTO. OK. We have a good kernel. Now, we have to set up software to our system. The call-back program is a part of mgetty-sendfax and ppp. You will find it all in your distribution. Because call-back system we have double verification and we create a user who will be running ppp on the side of server.

```
pppuser:klkIOM89mn65H:230:PPP Dialin:/home/pppuser:/etc/ppp/ppplogin
```

Then change the password. We have to add information about password in the file
`/etc/ppp/pap-secrets` (more in `man pppd`)

```
pppuser * password_for_pppuser *
```

This user doesn't have a usual shell but a file `/etc/ppp/ppplogin`. We have to make it ourselves. for example `vi /etc/ppp/ppplogin` and we type:

```
#!/bin/sh
```

```
exec /usr/sbin/pppd -detach 192.168.1.1:192.168.1.2
```

where the address 192.168.1.1 is the address of server with modem and the address 192.168.1.2 is the address which we assigned to our modem. We set up executable options for this file. Because we will use the ppp

call-back mini HOWTO

demon we have to set up the options for this demon. We edit file `/etc/ppp/options`:

```
netmask 255.255.255.0

proxyarp

lock

crtstcts

modem
```

Proxyarp is the most important from the above options, because you can go to Internet by the modem in the server. The remaining options are used control your modem. Your user can work only in local network if you remove proxyarp option. You have to see PPP-HOWTO and man pppd for more information. We will set up our modem now. Our server must be ready to receive a connection after start. We edit file `/etc/inittab` and we add it's to modem on the 2en com.

```
s1:2345:respawn:/sbin/mgetty ttyS1 -D /dev/ttyS1 vt100
```

For the 1st com line looks as follows:

```
s0:2345:respawn:/sbin/mgetty ttyS1 -D /dev/ttyS1 vt100
```

We make `init q`. If we don't have information about any mistakes in logs we go to the next step. We come back to directory `/etc/ppp` and create `options.ttyS1` (for modem com1 `options.ttyS0`)

```
IP_local: IP_remote
```

for our net it will be

```
192.168.1.1:192.168.1.2
```

We have done a lot work so far. Now, we check the file `/etc/mgetty+sendfax/login.config`. The most important line is:

```
/AutoPPP/ - a_ppp /usr/sbin/pppd auth -chap +pap login detach kdebug 7 debug
```

The remaining lines can be marked #.

We have to set up suid for ppp demon, because pppuser has to run pppd and make interface work.

```
chmod u+s /usr/sbin/pppd
```

and its effect is:

call-back mini HOWTO

```
-rwsr-xr-x 1 root root 106892 Jan 11 1999 /usr/sbin/pppd
```

I think that it is a good idea is to add it to cron because I had a problem after restart of my server pppd changed preference. Our server will work as router. We have to enable IP forwarding and we add this line for the file `/etc/rc.d/rc.local` :

```
echo "1" > /proc/sys/net/ipv4/ip_forward
```

If you are RedHat user you can change in `/etc/sysconfig/network` from `FORWARD_IPV4=false` to `FORWARD_IPV4=true`.

For verification we call to Linux. We use scripts for it. If we do this in MS Windows we mark options "call out a terminal after connection". We login as pppuser with its password. I hope that all is OK.

2.4 PART IV Linux calls us

We can already call our Linux. Now it's time Linux called us. It's not very difficult. We have to edit only two files. We create a file `/etc/mgetty+sendfax/callback.conf` and we leave it empty.

Then we have to ask our users for their phone number. It's time to write the numbers we have connected earlier. In order to do it we edit `/etc/mgetty+sendfax/login.conf` and add line:

```
call - - /usr/sbin/callback - S 123456
```

where call is a pseudo-user needed to initiate the connection. The line in the `/etc/mgetty+sendfax/login.conf` puts in motion the program calling the given number (in this case it's 123456). The same procedures can be applied to other users. I'll try to explain how it works. When we call a server. It asks us to give verification. We login as pseudo-user, in this case it calls. The script in our computer hangs up the modem. We wait and the connection is cut off. The program call-back starts working and recalls us. We verify ourselves again as pppuser with password. We combine the connection and interface ppp. That's all. The configuration of work-stations is very simple. When you have MS Windows, you have to install dial-up for your number. In the modem propriety we find " propriety--->extended--->extra options" where we write.

```
&c0s0=1
```

We close the window and call. We log in according to the description given above. If we want to use Linux, we must refer to the script. It's difficult to give only one good script for our Linux. A good configuration of ppp in the system is of primary importance. (You can call it as pppuser through the scripts first). The scripts below were written by A. Gozdz. I suggest putting everything to catalogue. It is only my suggestion & you don't have to start the scripts here. Detailed information concerning writing scripts on Linux can be found in PPP-HOWTO.

THESE SCRIPTS WORK WELL WITH SLACKWARE

The configuration file of daemon ppp (an example for modem on com2) `/etc/options`

```
lock
defaultroute
noipdefault
modem
/dev/cua1
33600
crtcts
debug
passive
asyncmap 0
```

and the specific scripts

- the first named `/etc/ppp/ppp-call`

```
#!/bin/bash

teksta="Connection failed"

tekstb="Probably, You will be connect"

# /sbin/setserial /dev/cua1 spd_vhi

killall -INT pppd 2>/dev/null

rm -f /var/lock/LCK* /var/run/ppp*.pid

(/usr/sbin/pppd -detach /dev/ttyS1 115200 \
connect "/usr/sbin/chat -v -f /etc/ppp/pppcallback" &) || \
(echo $teksta; ls marsss >/dev/null; exit 1)

echo $tekstb

exit 0
```

- the second file called `/etc/ppp/pppcallback`

```
TIMEOUT 60

ABORT 'ERROR'

ABORT 'BUSY'
```

call-back mini HOWTO

```
ABORT 'NO ANSWER'

ABORT 'NO DIALTONE'

ABORT '\nVOICE\r'

ABORT '\nRINGING\r\n\r\nRINGING\r'

' ' AT&FH0 <p>'OK-+++ \c-OK' 'AT&C0S0=1 '

TIMEOUT 75

OK ATDT123456

CONNECT ' '

'\nNO CARRIER\r' ' '

TIMEOUT 180

'\nRING\r' AT&C1A

CONNECT ' '

TIMEOUT 20

ogin:-ogin: pppuser

sword:-sword password_for_pppuser
• You can ppp-call, now. :)
```

THESE SCRIPTS WORK GOOD WITH LINUX RED HAT 6.x

- /etc/ppp/options
 - lock
 - defaultroute
 - noipdefault
 - modem
 - 33600
 - crtsets
 - debug
 - passive
 - asyncmap 0
- /etc/ppp/pppcallback
 - TIMEOUT 5

```

ogin:-ogin: ppp-pseudo-user

'\nNO CARRIER\r' ''

TIMEOUT 180

'\nRING\r' AT&C1A

CONNECT ''

TIMEOUT 20

ogin:-ogin: pppuser

sword:-sword password_for_ppuser
• /usr/bin/ppp-call

#!/bin/bash

teksta="Connection failed"

tekstb="Probably, You will be connect"

# /sbin/setserial /dev/cua1 spd_vhi

killall -INT pppd 2>/dev/null

rm -f /var/lock/LCK* /var/run/ppp*.pid

(/usr/sbin/pppd -detach call ppp_call &) || \

(echo $teksta; ls marsss >/dev/null; exit 1)

echo $tekstb

exit 0
• You can run ppp-call, now. :)

```

If you have M\$ Windows you can use this script for conection. I don't test it (I use terminal) you can ask some more Adrian Debkowski (adrian@cr-media.pl).

```
proc main

delay 1

waitfor "ogin:"

transmit "call^M"

waitfor "RING"

transmit "ATA^M"

waitfor "CONNECT"

waitfor "ogin:"

transmit "pppuser^M"

waitfor "word:"

transmit "ppp^M"

endproc
```

2.5 PART V Summary

The Configuration of call-back is not complicated. The most important thing is a proper arrangement of ppp server on Linux. I don't know a better way of setting up an access – server. The configuration presented above is a result of numerous attempts and it can be done in a different way. That's way I suggest reading all documents concerning this issue man pppd, NET4-HOWTO, PPP-HOWTO.
